Introduction

Traditional ML Approaches

Why Graph Neural Networks?

Graph Architecture

Dataset

Experimental Setup

Results

Conclusion

# INTRODUCTION

---

- Financial fraud is a growing issue, leading to billions of dollars in losses annually.
- Credit card fraud is the most common form of identity theft
- **Impact of Fraud:**
  - Erodes consumer trust.
  - Increases business operational costs.
  - Causes financial and legal challenges.
  - Affects economic stability.

## Choose the best model for financial fraud detection

### Traditional Models

Effective for tabular data

### Graph Neural Networks

Suitable for graph-based data

# CHALLENGES

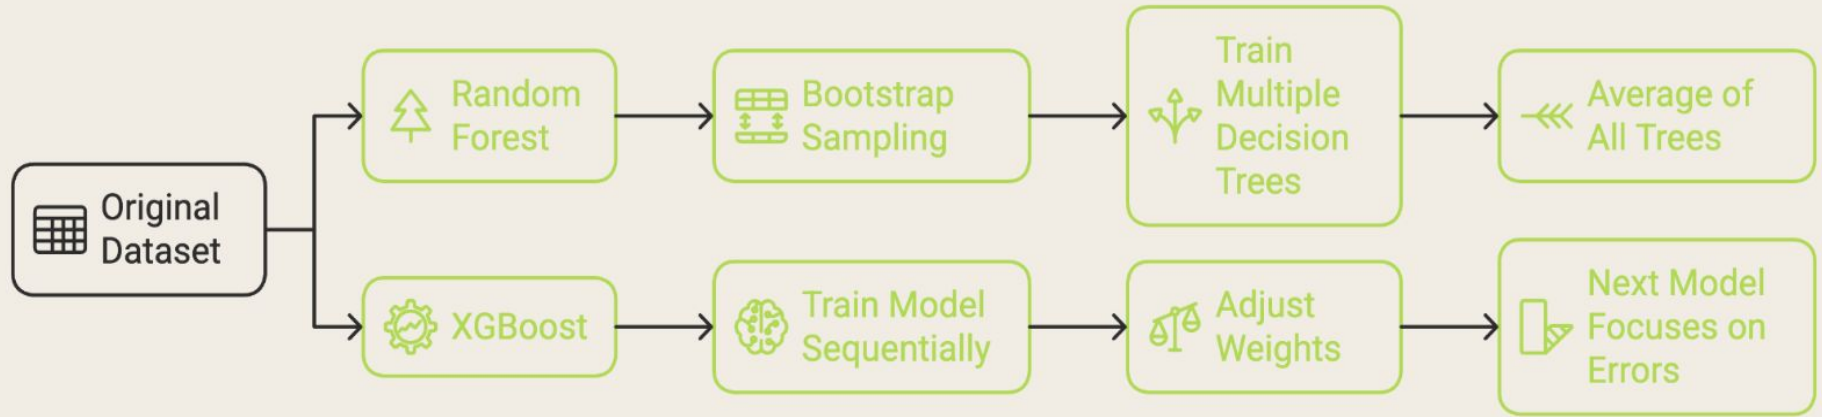

---

- Fraudsters are adaptive and change patterns
- Hard to get real-world data
- High imbalance in dataset
- Multiple accounts or cards being used
- The evolving complexity of fraud patterns.
- The critical role of model explainability

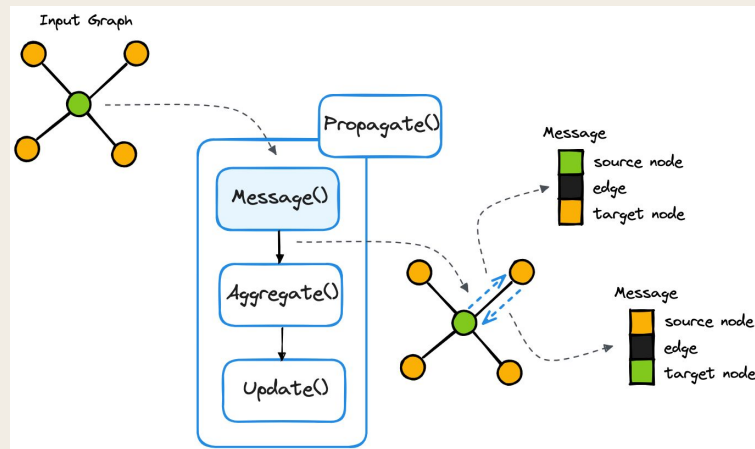

# TRADITIONAL ML MODELS

---

# Why Graph Neural Networks

- Transactions form a graph network
- GNNs learn from node embeddings and edge interactions, capturing hidden fraud patterns
- Traditional ML models treat transactions as independent instances, losing relational insights
- GNNs are capable of processing vast volumes of data

# Types of Graph

---

- **Homo-genous graph:**

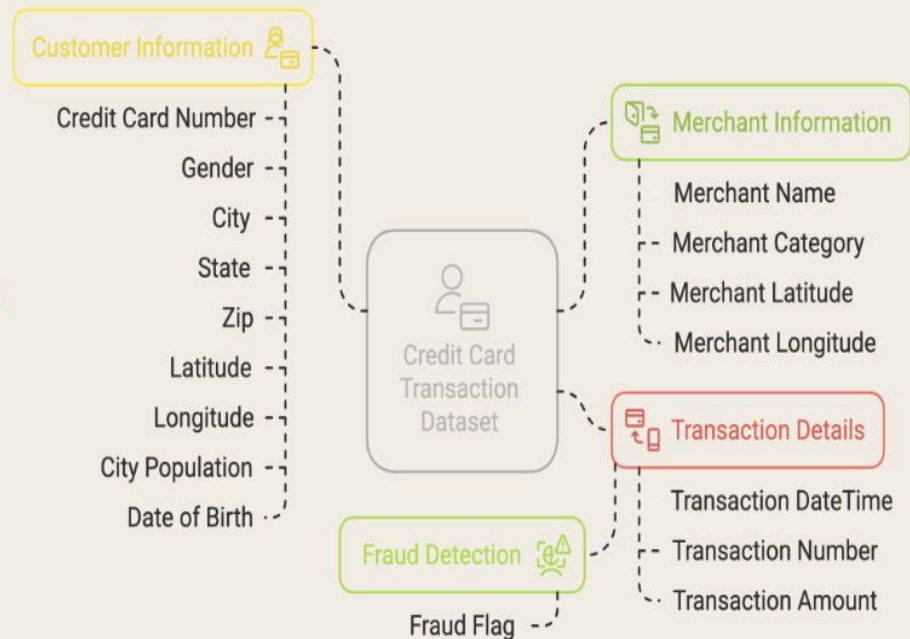

- A homogeneous graph consists of only **one type of node** and one type of edge.
- Simpler to train but does not capture different entity roles in the graph.
- Eg. **Social Network Analysis:** Nodes represent users, edges represent friendships.

- **Hetero-genous graph:**

- A heterogeneous graph consists of **multiple types of nodes** and edges, capturing more complex relationships.
- More complex but captures richer relationships.
- Implemented by HeteroGCN
- Eg. **Financial Fraud Detection:** Nodes represent Customers, Merchants, Transactions.

# DATASET

- Simulated credit card transaction dataset containing transactions from the duration 1st Jan 2019 - 31st Dec 2020.
- Covers credit cards of 1000 customers doing transactions with a pool of 800 merchants.
- Generated using Sparkov Data — Github tool created by Brandon Harris.

# DATA PREPROCESSING

- One-Hot Encoding: for low-cardinality features (e.g., device type).
- Label Encoding: for ordinal relationships (e.g., city size).
- Target Encoding: for high-cardinality features like merchant category

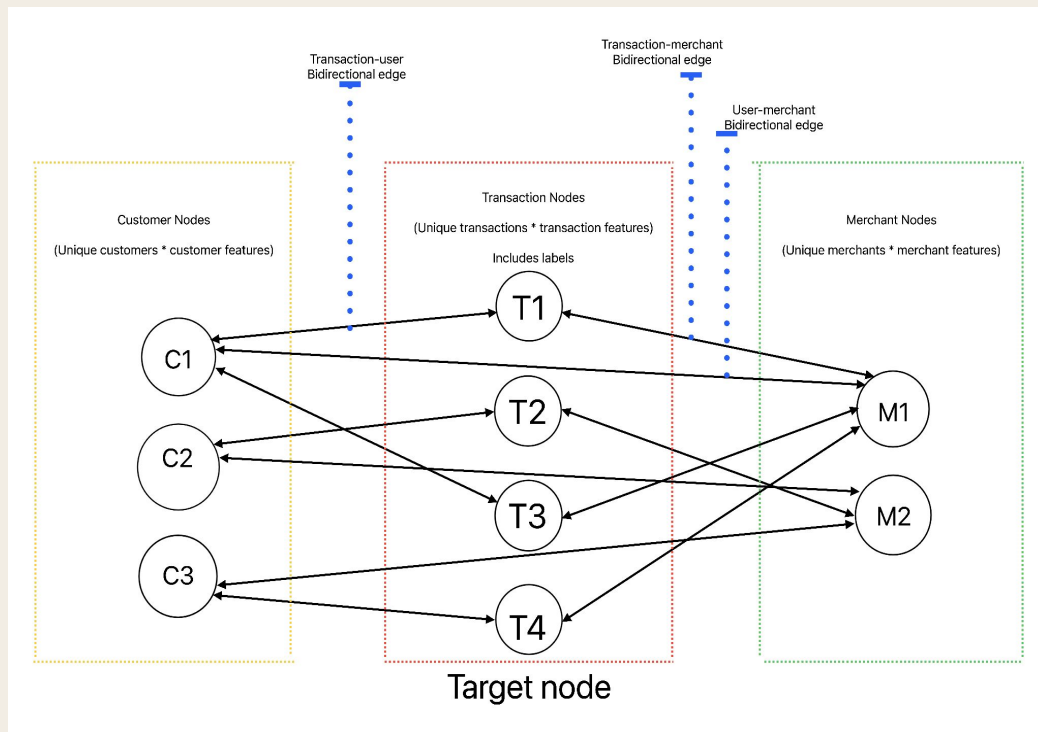

- Converted timestamp to datetime format.
- Extracted hour and day for temporal analysis.
- Applied sinusoidal encoding to preserve cyclic patterns

- Essential for creating Heterogeneous Graph using PyTorch Geometric

# GRAPH STRUCTURE

- Transaction nodes: 1296675
- Merchant nodes: 693
- Customer nodes: 983
- Edge type:
  - customer  $\leftrightarrow$  merchant: 479072
  - transaction  $\leftrightarrow$  customer: 1296675
  - transaction  $\leftrightarrow$  merchant: 1296675
  - transaction  $\leftrightarrow$  transaction: 1296675

# GNN Architecture

Customer

C1	C2	C3	C4	1	1	1	1	1	...	1	1
----	----	----	----	---	---	---	---	---	-----	---	---

Transaction

T1	T2	T3	T4	T5	T6	T7	T8	1	...	1	1
----	----	----	----	----	----	----	----	---	-----	---	---

Merchant

M1	M2	M3	1	1	1	1	1	1	...	1	1
----	----	----	---	---	---	---	---	---	-----	---	---

Customer

C'1	C'2	C'3	C'4	0.97	0.91	1.02	1.05	1.01	...	0.86	0.8
-----	-----	-----	-----	------	------	------	------	------	-----	------	-----

Transaction

T'1	T'2	T'3	T'4	T'5	T'6	T'7	T'8	1.1	...	0.97	1.13
-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	------	------

Merchant

M'1	M'2	M'3	0.8	1.2	0.92	1.14	...	...	...	1.3	0.93
-----	-----	-----	-----	-----	------	------	-----	-----	-----	-----	------

# EXPERIMENTAL SETUP

---

- Used 4 HeteroConv layers with GraphSAGE
- Embedding size of 32
- AWS EC2 - G5.2xlarge with 32 gb memory and GPU Accelerated due to millions of records
- Batch size of 128 yield best results with 60 epochs
- Used early-stopping with patience = 10 is used to avoid overfitting

# EVALUATION METRICS

---

- **AUC-PR:** measures the model's ability to correctly identify the positive class (fraud) across all threshold.
- **F1-score:** balances the trade-off between precision and recall, and is especially useful when both false positives and false negatives have significant consequences

# RESULTS

---

Methods	Precision	Recall	F1-Score	AUCPR
XGBoost	0.89	0.52	0.66	0.76
Random Forest	0.93	0.52	0.67	0.76
Decision Tree	0.60	0.68	0.64	0.41
Logistic Regression	0.00	0.00	0.00	0.13
GNN	0.73	0.65	<b>0.68</b>	0.47

Methods	Precision	Recall	F1-Score	AUCPR
XGBoost	0.92	0.75	<b>0.83</b>	0.92
Random Forest	0.93	0.72	0.81	0.90
Decision Tree	0.66	0.80	0.72	0.57
GNN	0.90	0.75	<b>0.82</b>	0.73

# CONCLUSION

---

- GNNs outperform classical models when relational structures dominate and feature engineering is limited.
- Heterogeneous message passing (users, merchants, transactions) boosts fraud detection performance.
- In Dataset 2, classical models (XGBoost, Random Forest) slightly outperformed due to strong, explicit features.
- GNNs excel in relationally complex, feature-sparse environments.
- Classical models remain strong when features are rich and well-crafted.

# FEEDBACK!
